Figure 1: Substrate relative observation proportions per survey year with manual faceting by groups defined by similarity. Similarity can further be specified as close relative proportion at survey year 8 or logical similarity, such as all herbaceous substrates, etc. Facet wrap was not used because I found that the faceted plots were too squished. Manual faceting with the patchwork package seemed to improve readability. I would have liked to have found a way to combine the x-axes and y-axes labels but with the blank plot in the bottom right made this difficult.

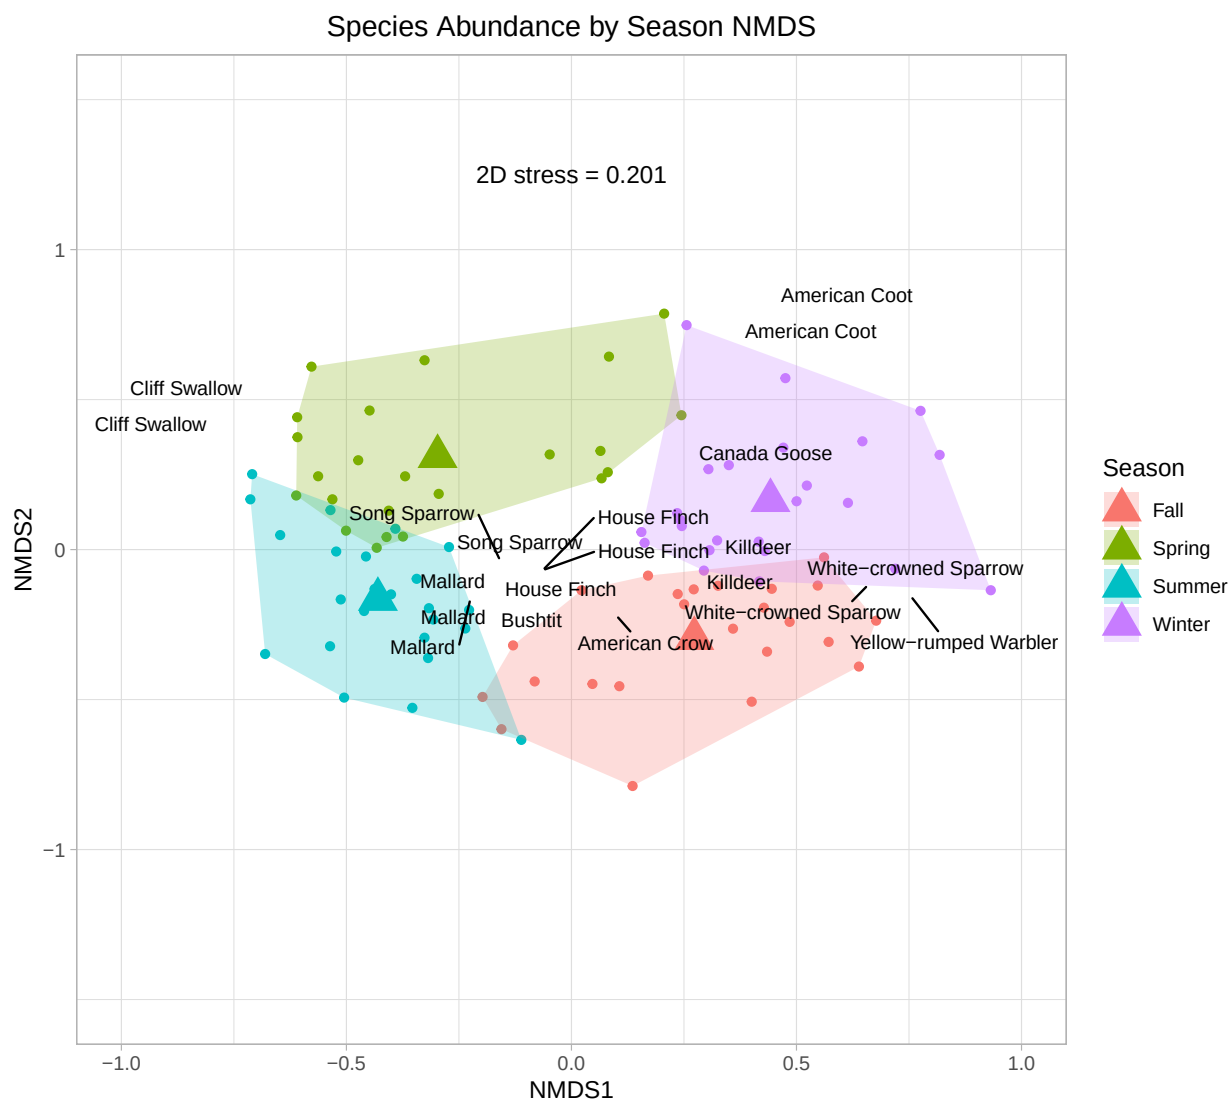

Figure 2: Seasons NMDS with the top 5 most abundant species per season included. Other than the addition of species, the figure is the same.

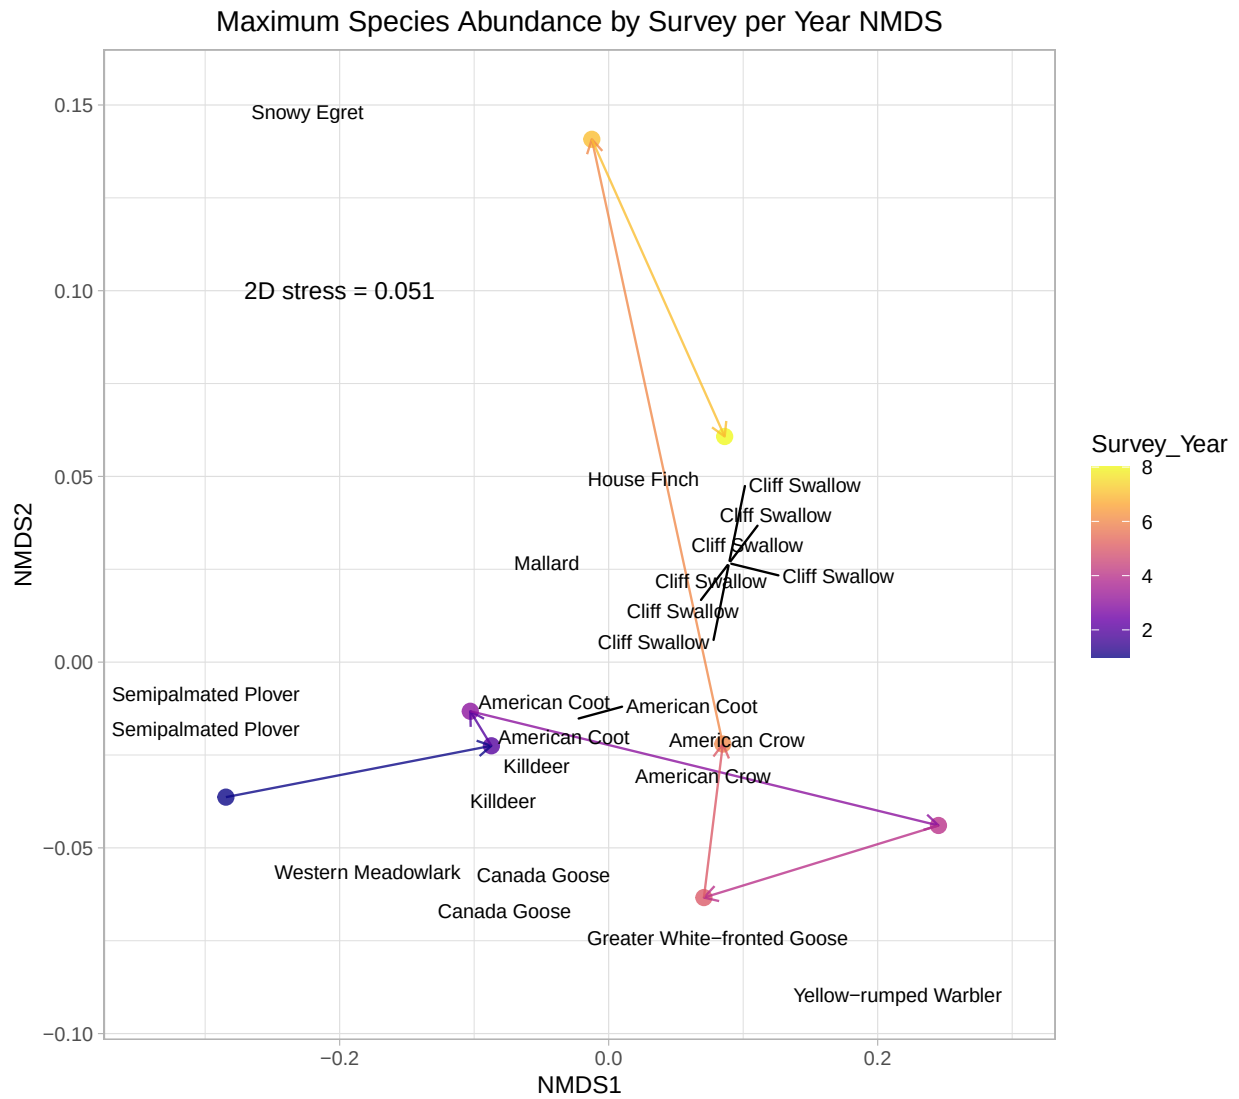

Figure 3: Maximum species abundance per survey per survey year NMDS with the top 3 greatest yearly maximum species per survey year included. Additionally, this NMDS now has a veridis color scale and arrows portraying the continuous progression of survey years, connecting the sites by continuous survey year.
